• Introduction

Student Dashboard is a menu-driven Python console application designed to provide three student-oriented utilities in one program: grade evaluation, attendance tracking, and FFCS slot calculation. The supplied source implements these utilities using basic Python constructs such as variables, lists, loops, conditional statements, formatted input/output, and arithmetic operations.

The program starts by displaying a **STUDENT DASHBOARD** menu with three choices. After completing a selected operation, the user is asked whether the program should continue. Entering N/n ends the loop and prints a thank-you message.

The report describes the project as implemented in the supplied source file; it does not assume a database, GUI, web server, or external package because none of those components appear in the source.

• **Problem Statement**

Students often need quick calculations related to academic performance and course registration. In the supplied project, these needs are addressed through a single console menu rather than separate manual calculations.

- **Grade evaluation**: compare each student's mark with the class average and assign a grade from S to F using the implemented ranges.
- **Attendance tracking**: calculate current attendance percentage and estimate classes that need to be attended or can be missed under the implemented 75% criterion.
- **FFCS assistance**: map a student's entered grade and total attendance to an FFCS slot according to the conditional rules encoded in the program.

The central problem addressed by the project is therefore the consolidation of these repeated student calculations into one interactive Python program.

• Functional Requirements

Requirement	Implemented Behaviour
Display main menu	Shows Grade Evaluation, Attendance Tracking, and FFCS options.
Accept menu choice	Reads the user's preference as an integer.
Evaluate grades	Collects course name, mark, and class average for each registered course.
Assign grade	Uses conditional ranges to append S/A/B/C/D/F.
Generate report card	Prints course, mark, class average, and calculated grade.
Calculate attendance	Computes current attendance as $\text{attended/scheduled} \times 100$.
Check 75% criterion	Calculates attendance requirements using scheduled and upcoming classes.
Calculate FFCS slot	Uses grade and attendance combinations to print a slot number.
Repeat or exit	Asks for Y/N and continues unless N/n is entered.

• **Non-Functional Requirements**

- **Usability**: the application uses clear console prompts and a numbered menu.
- **Simplicity**: the source is a single Python script and uses fundamental language features.
- **Portability**: no external libraries or database are referenced in the supplied source, so the program is designed around standard Python console I/O.
- **Maintainability**: the three major functions are separated logically through menu branches, although they are implemented in one script rather than separate functions/modules.
- **Performance**: the calculations are small and operate on user-entered values, so no substantial computational workload is present.
- **Data persistence**: none is implemented; course and attendance information exists only during the current execution.

• System Architecture

The supplied implementation follows a simple single-process, menu-driven architecture. There is no client/server layer, persistent storage layer, or external service. User input is read from the console, processed inside conditional branches, and the result is printed back to the console.

Architecture flow: Student → Main Menu Controller → selected utility → calculation/decision logic → console result → Continue/Exit.

• Design diagrams

1. USE CASE DIAGRAM

2. WORKFLOW DIAGRAM

3. CLASS / COMPONENT DIAGRAM

<u>Component</u>	<u>Responsibility</u>
<u>Main loop</u>	<u>Displays menu, reads choice, repeats or exits.</u>
<u>Grade evaluation branch</u>	<u>Stores courses, marks, averages and calculated grades in lists.</u>
<u>Attendance branch</u>	<u>Calculates percentage and attendance requirements.</u>
<u>FFCS branch</u>	<u>Matches grade + attendance conditions to an FFCS slot.</u>
<u>Console I/O</u>	<u>Collects user input and displays results.</u>

• **Design Decisions & Rationale**

- Console interface: the source uses input() and print(), making the application straightforward to run from a Python terminal.
- Menu-driven design: one top-level choice routes the user to one of three student utilities.
- Lists for course data: all_courses, mis, ais, and grade store parallel per-course information during grade evaluation.
- Conditional grading: the grade is determined by comparing the student's mark with the class average, rather than by a fixed absolute mark threshold.
- 75% attendance target: the attendance branch explicitly uses 75/100 in its semester-end calculation.
- Direct FFCS mapping: grade and attendance are handled with a chain of if/elif conditions, keeping the mapping visible in the source.

- **Implementation Details**

The report card then prints each course, scored mark, class average, and grade.

- **ATTENDANCE TRACKING**

Current attendance is calculated as **(classes attended / classes scheduled) × 100**. The program also calculates a semester-end 75% target using the current scheduled classes plus upcoming classes, then derives how many upcoming classes need to be attended and how many may be missed under the implemented arithmetic.

- **FFCS SLOT CALCULATION**

The FFCS branch reads total attendance and a grade, converts the grade to lowercase, and checks grade/attendance combinations. It prints slot numbers from 1 through 8 for the combinations explicitly represented in the source.

- **Program Control**

After each selected operation, the program asks **PRESS Y/N ENTER TO CONTINUE**. A Y/y input continues the outer loop. An N/n input causes the loop condition to fail and the program prints **THANK YOU**.

• Testing Approach

The testing approach is organized around menu coverage, boundary values, and invalid/edge conditions. The expected outcomes below are derived from the current logic.

Important boundary observations from the source: the attendance branch checks a $< 75\%$ and a $> 75\%$ condition, so exactly 75% is not covered by either branch and falls to the final else. The FFCS branch also contains a repeated D-grade condition near the end and does not include a separate F-grade mapping. These are source-level behaviours to consider during testing

Input / Scenario	Expected behaviour
Choose 1; enter one course and mark at least 10 above average	Grade branch should assign S.
Choose 1; mark exactly average + 5	Grade branch should assign A.
Choose 1; mark within the implemented B interval around the a	verageGrade branch should assign B.
Choose 2; attended < 75%	
Choose 2; attended > 75%	Program enters the above-criteria message when its additional condition is satisfied.

Choose 3; grade S and attendance ≥ 90	Prints FFCS SLOT => 1.
Choose 3; grade A and attendance 75–84.99	Prints FFCS SLOT => 3.
Choose 3; grade D and attendance 80–84.99	Prints FFCS SLOT => 6.
Choose invalid menu option	Prints “Enter Valid Choice!”.
After an operation enter N/n	Exits loop and prints “THANK YOU”.

• Challenges Faced

- **Multiple input types**: the program accepts integers for menu choices and counts, floats for class averages and attendance, and strings for course names and grades.
- **Boundary conditions**: grade and attendance decisions depend on ranges, so exact threshold values require careful testing.
- **Parallel lists**: grade evaluation keeps related course information in separate lists and relies on matching indexes.
- **Complex FFCS branching**: the long if/elif chain makes it important to keep grade and attendance intervals consistent.
- **Input validation**: the current implementation assumes numeric input can be converted successfully; invalid text for integer/float prompts can raise a Value Error.
- **Documentation consistency**: some inline comments describe conditions inaccurately compared with the actual code, so the executable statements are the authoritative implementation.

• Learnings and Key Takeaways

- Applied Python fundamentals: variables, lists, loops, conditionals, input/output, arithmetic, and string methods.
- Learned how nested/ordered if-elif conditions implement rule-based decision systems.
- Practiced collecting repeated records with a for loop and storing them in lists.
- Understood how attendance percentages and target calculations can be translated into program logic.
- Observed the importance of boundary-value testing for grading and attendance rules.
- Gained experience designing a small menu-driven command-line application.

• Future Enhancement

- **Refactor into functions**: create separate functions such as `grade_evaluation()`, `attendance_tracker()`, and `ffcs_calculator()`.
- **Improve validation**: safely handle non-numeric input, invalid grades, negative values, and attendance above 100%.
- **Fix boundary behaviour**: explicitly handle exactly 75% attendance and review all grade/attendance endpoints.
- **Use structured data**: replace parallel lists with dictionaries or a small Course class/data structure.
- **Add persistence**: save student/course information in a file or database if required.
- **Add a GUI**: provide forms and buttons for users who prefer a graphical interface.
- **Improve FFCS rules**: represent slot rules as structured data so they are easier to update and test.
- **Add automated tests**: use Python's unit test or python test to test each grade, attendance, and FFCS boundary.
- **Improve reporting**: export the report card and attendance summary to CSV/PDF
